Isotropy Groups of Quasi-Equational Theories

Jason Parker (joint with Pieter Hofstra and Philip Scott, University of Ottawa)

> Brandon University Brandon, Manitoba, Canada

Vanderbilt Universal Algebra and Logic Seminar December 7, 2020

Introduction

- **Isotropy** is a (new) mathematical phenomenon with manifestations in category theory, universal algebra, and theoretical computer science.
- We will see that isotropy encodes a generalized notion of *conjugation* or *inner automorphism* for (quasi-)equational theories.

Motivation

Recall that an automorphism α of a group G is *inner* if there is an element s ∈ G such that α is given by *conjugation* with s, i.e.

$$(g \in G)$$
 $\alpha(g) = sgs^{-1}.$

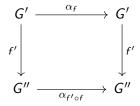

• It turns out that the inner automorphisms of a group can be characterized *without* mentioning conjugation or group elements at all!

Motivation

• To see this, observe first that if α is an inner automorphism of a group G (induced by $s \in G$), then for each group morphism $f : G \to H$ with domain G we can 'push forward' α to define an inner automorphism

$$\alpha_f: H \xrightarrow{\sim} H$$

by conjugation with $f(s) \in H$ (so that $\alpha_{id_G} = \alpha$), and this family of automorphisms $(\alpha_f)_f$ is *coherent*, in the sense that it satisfies the following *naturality* property: if $f: G \to G'$ and $f': G' \to G''$ are group homomorphisms, then the following diagram commutes:

Bergman's Theorem

For a group G, let us call an *arbitrary* family of automorphisms

$$\left(\alpha_f: \operatorname{cod}(f) \xrightarrow{\sim} \operatorname{cod}(f)\right)_{\operatorname{dom}(f)=0}$$

with the above naturality property an extended inner automorphism of G.

Theorem (Bergman [1])

Let G be a group and $\alpha : G \xrightarrow{\sim} G$ an automorphism of G. Then α is an **inner** automorphism of G iff there is an extended inner automorphism $(\alpha_f)_f$ of G with $\alpha = \alpha_{id_G}$.

This provides a completely *element-free* characterization of inner automorphisms of groups! They are exactly those group automorphisms that are 'coherently extendible' along morphisms out of the domain.

Covariant Isotropy

- We have a functor Z : Group → Group that sends any group G to its group of extended inner automorphisms Z(G). We refer to Z as the covariant isotropy group (functor) of the category Group.
- In fact, any category $\mathbb C$ has a covariant isotropy group (functor)

 $\mathcal{Z}_{\mathbb{C}}:\mathbb{C}\to \text{Group}$

that sends each object $C \in \mathbb{C}$ to the group of extended inner automorphisms of C, i.e. families of automorphisms

$$\left(\alpha_f: \operatorname{cod}(f) \xrightarrow{\sim} \operatorname{cod}(f)\right)_{\operatorname{dom}(f)=C}$$

in \mathbb{C} with the same naturality property as before, i.e. natural automorphisms of the projection functor $C/\mathbb{C} \to \mathbb{C}$.

Covariant Isotropy

- We can also turn Bergman's characterization of inner automorphisms in Group into a *definition* of inner automorphisms in an arbitrary category C: if C ∈ C, we say that an automorphism α : C → C is *inner* if there is an extended inner automorphism (α_f)_f ∈ Z_C(C) with α_{id_c} = α.
- Notice that Group is the category of (set-based) models of an algebraic theory, i.e. a set of equational axioms between terms, namely the theory T_{Grp} of groups. So Group = T_{Grp}mod.
- We will generalize ideas from the proof of Bergman's Theorem to give a 'syntactic' characterization of the (extended) inner automorphisms of **Tmod**, i.e. of the covariant isotropy group of **Tmod**, for any so-called *quasi-equational* theory **T**.

Quasi-Equational Theories

- What is a quasi-equational theory? (a.k.a. a partial Horn theory or essentially algebraic theory.)
- First, we need the notion of a signature Σ, which consists of a non-empty set Σ_{Sort} of sorts, and a set Σ_{Fun} of (typed) function/operation symbols.
- For example, the signature for groups has one sort X and three function symbols · : X × X → X, ⁻¹ : X → X, and e : X. The signature for categories has two sorts O, A and four function symbols dom, cod : A → O, id : O → A, and ∘ : A × A → A.

Quasi-Equational Theories

- We can then form the set Term(Σ) of terms over Σ, constructed from variables and function symbols, as well as the set Horn(Σ) of Horn formulas over Σ, which are finite conjunctions of equations between terms.
- A quasi-equational theory over a signature Σ is then a set of implications (the axioms of T) of the form φ ⇒ ψ, with φ, ψ ∈ Horn(Σ) (see [6]).
- The operation symbols of a quasi-equational theory are only required to be *partially* defined. If t is a term, we write t ↓ as an abbreviation for t = t, meaning 't is defined'.

• Any algebraic theory, whose axioms all have the form $\top \Rightarrow \psi$, where \top is the empty conjunction. E.g. the theories of sets, semigroups, (commutative) monoids, (abelian) groups, (commutative) rings with unit, etc. For example, the theory \mathbb{T}_{Grp} of groups has the following axioms:

$$T \Rightarrow x \cdot y \downarrow \land x^{-1} \downarrow \land e \downarrow,$$

$$T \Rightarrow x \cdot (y \cdot z) = (x \cdot y) \cdot z,$$

$$T \Rightarrow x \cdot e = x \land e \cdot x = x,$$

$$T \Rightarrow x \cdot x^{-1} = e \land x^{-1} \cdot x = e.$$

• The theories of categories and groupoids. E.g. two of the axioms are

```
g \circ f \downarrow \Rightarrow \operatorname{\mathsf{dom}}(g) = \operatorname{\mathsf{cod}}(f),
```

$$\mathsf{dom}(g) = \mathsf{cod}(f) \Rightarrow g \circ f \downarrow .$$

- The theory of strict monoidal categories.
- The theory of functors $\mathcal{J} \to \mathbb{T}$ **mod** for a small category \mathcal{J} and quasi-equational theory \mathbb{T} . In particular, the theory of presheaves $\mathcal{J} \to \mathbf{Set}$.

Proof of Bergman's Theorem

- Let us focus on a specific idea in the proof of Bergman's Theorem.
- Consider the group G(x) obtained from G by freely adjoining an indeterminate element x. Elements of G(x) are (reduced) group words in x and elements of G.
- The underlying set of G⟨x⟩ can be endowed with a substitution monoid structure: given w₁, w₂ ∈ G⟨x⟩, we set w₁ ⋅ w₂ to be the reduction of w₁[w₂/x], and the unit is x itself.
- If $w \in G(\mathbf{x})$, w commutes generically with the group operations if:
 - In $G\langle \mathbf{x}_1, \mathbf{x}_2 \rangle$, the reduction of $w[\mathbf{x}_1/\mathbf{x}]w[\mathbf{x}_2/\mathbf{x}]$ is $w[\mathbf{x}_1\mathbf{x}_2/\mathbf{x}]$;
 - In $G\langle \mathbf{x} \rangle$, the reduction of w^{-1} is $w[\mathbf{x}^{-1}/\mathbf{x}]$;
 - In $G\langle \mathbf{x} \rangle$, the reduction of $w[e/\mathbf{x}]$ is e.

Proof of Bergman's Theorem

E.g. if g ∈ G, then the word gxg⁻¹ ∈ G⟨x⟩ commutes generically with the group operations:

•
$$g\mathbf{x}_1g^{-1}g\mathbf{x}_2g^{-1} \sim g\mathbf{x}_1\mathbf{x}_2g^{-1}$$

• $(g\mathbf{x}g^{-1})^{-1} \sim (g^{-1})^{-1}\mathbf{x}^{-1}g^{-1} \sim g\mathbf{x}^{-1}g^{-1}$,

•
$$geg^{-1} \sim gg^{-1} \sim e$$
.

- Let Z(G) be the group of extended inner automorphisms of G, and let Inv(G⟨x⟩) be the subgroup of *invertible* elements of the substitution monoid G⟨x⟩. (E.g. gxg⁻¹ is invertible, with inverse g⁻¹xg.)
- Then the proof of Bergman's Theorem shows that the group Z(G) is isomorphic to the subgroup of Inv(G(x)) consisting of all words that commute generically with the group operations.

The Isotropy Group of a Quasi-Equational Theory

- Fix a quasi-equational theory T over a signature Σ, and let Tmod be the category of (set-based) models of T. For simplicity, we will generally assume (in this talk) that T is single-sorted.
- We will now give a *logical/syntactic* characterization of the covariant isotropy group

 $\mathcal{Z}_{\mathbb{T}}:\mathbb{T}\text{mod}\rightarrow\text{Group}$

of $\mathbb{T}\mathbf{mod}$.

Fix M ∈ Tmod. As for groups, we can construct a T-model M⟨x⟩, which is the coproduct of M with the free T-model on one generator x. Elements of M⟨x⟩ are (equivalence classes of) Σ-terms over x and elements of M. We can then endow the underlying set of M⟨x⟩ with a substitution monoid structure, in the same way as for groups.

The Isotropy Group of a Quasi-Equational Theory

In my thesis, I proved:

Theorem ([7])

Let \mathbb{T} be a quasi-equational theory over a (single-sorted) signature Σ . For any $M \in \mathbb{T}$ **mod**, the covariant isotropy group $\mathcal{Z}_{\mathbb{T}}(M)$, i.e. the group of extended inner automorphisms of M, is isomorphic to the group of **invertible** elements t of the substitution monoid $M\langle \mathbf{x} \rangle$ that **commute generically with** the function symbols of Σ , in the sense that if f is any *n*-ary function symbol of Σ , then

$$t[f(\mathbf{x}_1,\ldots,\mathbf{x}_n)/\mathbf{x}] = f(t[\mathbf{x}_1/\mathbf{x}],\ldots,t[\mathbf{x}_n/\mathbf{x}])$$

holds in $M\langle x_1, \ldots, x_n \rangle$ (the coproduct of M with the free \mathbb{T} -model on n generators x_1, \ldots, x_n).

The Isotropy Group of a Quasi-Equational Theory

 In particular, an automorphism α : M → M in Tmod is inner iff there is some t ∈ Z_T(M) that induces α, i.e.

$$(m \in M)$$
 $\alpha(m) = t[m/\mathbf{x}] \in M.$

 Thus, Bergman's (syntactic) characterization of the (extended) inner automorphisms of Group = T_{Grp}mod extends to the category Tmod of (set-based) models of *any* quasi-equational theory T!

- If T is the theory of sets, then T has trivial isotropy group, i.e.
 Z_T(S) ≅ {x} for any set S, so the only inner automorphism of a set is the *identity* function.
- If \mathbb{T} is the theory of groups, then Bergman proved $\forall G \in \mathbb{T}$ mod = Group that

$$\mathcal{Z}_{\mathbb{T}}(G)\cong \{g\mathbf{x}g^{-1}\in G\langle \mathbf{x}
angle \ \mid g\in G\}\cong G.$$

• If \mathbb{T} is the theory of monoids, then $\forall M \in \mathbb{T}\mathbf{mod} = \mathbf{Mon}$ we have

 $\mathcal{Z}_{\mathbb{T}}(M) \cong \{m\mathbf{x}m^{-1} \in M \langle \mathbf{x} \rangle \mid m \text{ is invertible in } M\} \cong \mathbf{Inv}(M).$

• If $\mathbb T$ is the theory of abelian groups, then $\forall {\it G} \in \mathbb T{\it mod} = {\it Ab}$ we have

$$\mathcal{Z}_{\mathbb{T}}(G)\cong \{\mathbf{x},-\mathbf{x}\}\cong \mathbb{Z}_2.$$

- If $\mathbb T$ is the theory of commutative monoids or unital rings, then the isotropy group of $\mathbb T$ is trivial.
- If \mathbb{T} is the theory of (not necessarily commutative) unital rings, then $\forall R \in \mathbb{T}$ **mod** = **Ring** we have

$$\mathcal{Z}_{\mathbb{T}}(R) \cong \{ r \mathbf{x} r^{-1} \in R \langle \mathbf{x} \rangle \mid r \in R \text{ is a unit} \} \cong \mathsf{Unit}(R).$$

• If $\mathbb T$ is the theory of categories or groupoids, then the isotropy group of $\mathbb T$ is trivial.

• If $\mathbb T$ is the theory of strict monoidal categories, then for any strict monoidal category $\mathbb C$ we have

$$\mathcal{Z}_{\mathbb{T}}(\mathbb{C})\cong \mathsf{Inv}\left(\mathbb{C}_{\mathcal{O}},\otimes^{\mathbb{C}},e^{\mathbb{C}}
ight),$$

the group of invertible elements of the object monoid $(\mathbb{C}_O, \otimes^{\mathbb{C}}, e^{\mathbb{C}})$ of \mathbb{C} . In particular, if $F : \mathbb{C} \xrightarrow{\sim} \mathbb{C}$ is a (strict monoidal) automorphism of a strict monoidal category \mathbb{C} , then F is *inner* iff there is some invertible object $c \in \mathbb{C}$ such that F is given by *conjugation* with c, i.e.

$$(a \in \mathbb{C}_O) \qquad \qquad F(a) = c \otimes a \otimes c^{-1}$$

and

$$(f \in \mathbb{C}_A)$$
 $F(f) = \mathrm{id}_c \otimes f \otimes \mathrm{id}_{c^{-1}}.$

Some Closure Properties

Let T be a quasi-equational theory over a (single-sorted) signature Σ, let c ∉ Σ be a new constant symbol, and let T_c be the theory over the signature Σ ∪ {c} with the same axioms as T. Then for any M ∈ Tmod and c^M ∈ M, we have

$$\mathcal{Z}_{\mathbb{T}_c}\left(M, c^M\right) \cong \left\{ (\alpha_f)_f \in \mathcal{Z}_{\mathbb{T}}(M) : \alpha_{\mathrm{id}_M}\left(c^M\right) = c^M \right\}.$$

 Let T be a quasi-equational theory over a (single-sorted) signature Σ, let f ∉ Σ be a new *non-constant* function symbol, and let T_f be the theory over the signature Σ ∪ {f} with the same axioms as T. Then the covariant isotropy group of T_f is *trivial*.

Some Closure Properties

• Let \mathbb{T}_1 and \mathbb{T}_2 be quasi-equational theories over disjoint signatures Σ_1 and Σ_2 , and let $\mathbb{T}_1 + \mathbb{T}_2$ be the *union* of the theories \mathbb{T}_1 and \mathbb{T}_2 . Then

$$\mathcal{Z}_{\mathbb{T}_1+\mathbb{T}_2}\cong \mathcal{Z}_{\mathbb{T}_1}\times \mathcal{Z}_{\mathbb{T}_2}.$$

Isotropy Groups of Functor Categories

- We can also characterize the covariant isotropy groups of *functor* categories of the form $\mathbb{T}\mathbf{mod}^{\mathcal{J}}$, for a quasi-equational theory \mathbb{T} and small category \mathcal{J} . In particular, we can characterize the covariant isotropy groups of presheaf categories $\mathbf{Set}^{\mathcal{J}}$.
- Fix a quasi-equational theory \mathbb{T} . Given a small category \mathcal{J} , we can define a quasi-equational theory $\mathbb{T}^{\mathcal{J}}$ whose models are functors $\mathcal{J} \to \mathbb{T}\mathbf{mod}$, i.e.

 $\mathbb{T}^{\mathcal{J}}\mathsf{mod}\cong\mathbb{T}\mathsf{mod}^{\mathcal{J}}.$

Isotropy Groups of Functor Categories

In my thesis, I then proved the following theorem:

Theorem ([7])

Let \mathbb{T} be a (single-sorted) quasi-equational theory (satisfying a few technical assumptions), and let \mathcal{J} be a small category, with $\operatorname{Aut}(\operatorname{Id}_{\mathcal{J}})$ the group of natural automorphisms of $\operatorname{Id}_{\mathcal{J}} : \mathcal{J} \to \mathcal{J}$ (which we may call the global isotropy group of \mathcal{J}). For any functor $F : \mathcal{J} \to \mathbb{T}$ mod, we have

 $\mathcal{Z}_{\mathbb{T}\mathsf{mod}^{\mathcal{J}}}(F)\cong\mathsf{lim}(\mathcal{Z}_{\mathbb{T}}\circ F)\times\mathsf{Aut}(\mathsf{Id}_{\mathcal{J}})\in\mathsf{Group}.$

In particular, for any functor $F : \mathcal{J} \to \mathbf{Set}$, we have

$$\mathcal{Z}_{\mathbf{Set}^{\mathcal{J}}}(F) \cong \mathbf{Aut}(\mathbf{Id}_{\mathcal{J}}).$$

Isotropy Groups of Functor Categories

In particular, if F : J → Set is a functor and α : F → F is an automorphism, then α is inner iff there is some ψ ∈ Aut(Id_J) with

$$(k \in \mathcal{J})$$
 $\alpha_k = F(\psi_k) : F(k) \xrightarrow{\sim} F(k).$

So the covariant isotropy group functor Z : Set^J → Group is constant on the global isotropy group Aut(Id_J) of J.

Isotropy Groups of G-Sets

- For any group G, the covariant isotropy group functor
 Z : Set^G → Group of the category of G-sets is constant on the centre Z(G) of the group G.
- More generally, for any monoid *M*, the covariant isotropy group functor *Z* : Set^M → Group of the category of *M*-sets is *constant* on the group Inv(*Z*(*M*)) of invertible elements of the centre of *M*.

Connections with Topos Theory

- If T is a quasi-equational theory, then T has a *classifying topos* $\mathcal{B}(\mathbb{T})$, which is a cocomplete topos that has a *universal model* of T and classifies all topos-theoretic models of T ([4], [5]).
- It has been shown that any Grothendieck topos \mathcal{E} has a canonical internal group object called the *isotropy group* of the topos, which acts canonically on every object of the topos and formally generalizes the notion of conjugation ([3]).
- The covariant isotropy group Z_T of a quasi-equational theory T is in fact the isotropy group object of the classifying topos B(T) of T ([3], [4]).

Conclusions

- Bergman's *element-free* characterization of the inner automorphisms of groups can be used to *define* inner automorphisms in arbitrary categories.
- We have extended Bergman's syntactic characterization of the (extended) inner automorphisms of groups, i.e. of the covariant isotropy group of Group = T_{Grp}mod, to the covariant isotropy group of Tmod for any quasi-equational theory T.
- Using this characterization, we have obtained concrete descriptions of the (extended) inner automorphisms in several different categories:
 Set, Group, Mon, Ab, Ring, Cat, StrMonCat, Tmod^J, Set^J, ...
- This work also represents a contribution to the more general project of characterizing the isotropy group objects of Grothendieck toposes.

Some Future Directions

- Given (disjoint) theories \mathbb{T}_1 and \mathbb{T}_2 , characterize the covariant isotropy group of the category of models of \mathbb{T}_1 in \mathbb{T}_2 mod (i.e. the category of models of $\mathbb{T}_1 \otimes \mathbb{T}_2$) in terms of the covariant isotropy groups of \mathbb{T}_1 and \mathbb{T}_2 (subsuming the examples of strict monoidal categories and functor categories $\mathbb{T}\mathbf{mod}^{\mathcal{J}}$). This is current work in progress.
- Which aspects of the theory of conjugation can be extended/generalized from the theory of groups to arbitrary quasi-equational theories?
- Characterize covariant isotropy *monoids*, in connection with Freyd's notion of core algebras ([2]) in the study of polymorphism.

Thank you!
