Lattice Paths

State space: All **monotonic lattice paths** from $(0,0)$ to (n,n) .

Local dynamics: Switch between “**mountains**” and “**valleys**”.

Lattice Paths

Simple Exclusion Processes

Card Shuffling with Nearest Neighbor Transpositions

0	1	0	0	0	0	0
0	1	0	0	1	0	0
0	1	0	1	1	0	0
0	1	0	1	1	1	0
0	1	0	1	1	1	1
1	1	0	1	1	1	1

Integer Partitions

An **Integer Partition** of n is a sum of positive integers where order doesn't matter ($4 + 6$ is the same as $6 + 4$).

Ex: $1 + 1 + 4 + 5$, $3 + 3 + 5$, and 11 are partitions of 11.

Integer Partitions

Ferrers (Young) Diagrams:

Each piece of the partition is represented as an ordered “stack” of squares.

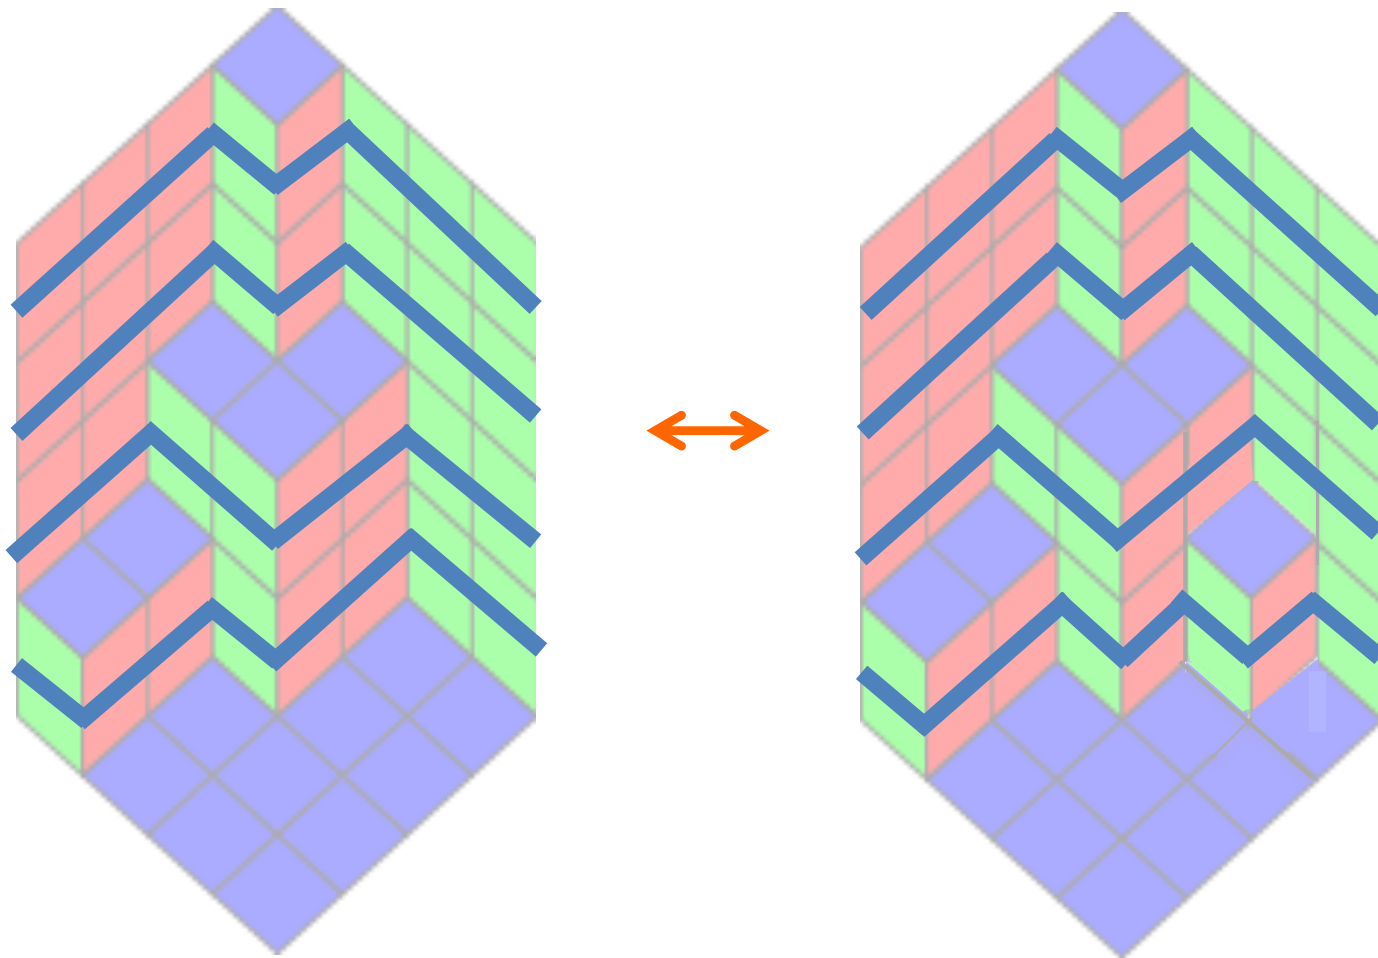

Sampling integer partitions of n is the same as sampling **lattice paths** bounding regions of **area n** .

Multiple Nonintersecting Paths

Multiple Nonintersecting Paths

Vertex Disjoint Paths = Lozenge Tilings

Repeat:

- Pick **v** in the lattice region;
- **Add / remove** the “cube” at **v** w.p. $\frac{1}{2}$, if possible.

There is a bijection between **nonintersecting lattice paths** and **lozenge tilings** (or **dimer coverings**).

Or, If *Edge* Disjoint...

Crossing path:

D, R: +1 (mod 3)

U, L: -1

No path:

D, R: -1

U, L: +1

3-Colorings (or Eulerian Orientations)

0	2	0	1	2
2	0	2	0	1
0	1	0	1	0
1	0	1	0	2
0	1	0	2	1

Crossing path:
D, R: +1 (mod 3)
U, L: -1

No path:
D, R: -1
U, L: +1

There is a bijection between **edge disjoint lattice paths** and **proper 3-colorings of \mathbb{Z}^2** (and the “**6-vertex model**”).

Repeat:

- Pick a cell uniformly;
- Recolor the cell w.p. $\frac{1}{2}$, if possible.

Q: How do we sample lattice paths?

3-colorings

Lattice Paths in \mathbb{Z}^2

To sample, repeat:

- Pick v on the path;
- If v is a mountain/valley, invert w.p. $\frac{1}{2}$ (if possible).

This Markov chain is reversible and ergodic, so it converges to the uniform distribution over lattice paths.

How long?

Answer: $\Theta(n^3 \log n)$ [Wilson]

The mixing time

Def: The **total variation distance** is

$$\|P^t, \pi\| = \max_{x \in \Omega} \frac{1}{2} \sum_{y \in \Omega} |P^t(x, y) - \pi(y)|.$$

Def: Given ε , the **mixing time** is

$$\tau(\varepsilon) = \min \{t: \|P^t, \pi\| < \varepsilon, \forall t' \geq t\}.$$

A Markov chain is **rapidly mixing** if $\tau(\varepsilon)$ is **poly**($n, \log(\varepsilon^{-1})$).
(or **polynomially mixing**)

A Markov chain is **slowly mixing** if $\tau(\varepsilon)$ is at least **exp**(n).

Coupling

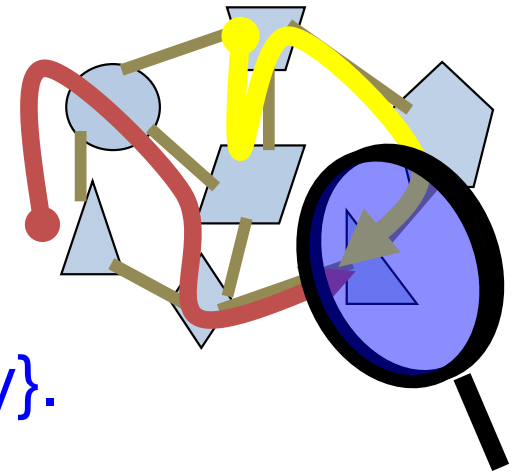

Definition: A **coupling** is a MC on $\Omega \times \Omega$:

- 1) Each process $\{X_t\}, \{Y_t\}$ is a faithful copy of the original MC;
- 2) If $X_t = Y_t$, then $X_{t+1} = Y_{t+1}$.

The **coupling time** T is:

$$T = \max_{x,y} (E [T^{x,y}]),$$

where $T^{x,y} = \min \{t: X_t=Y_t \mid X_0=x, Y_0=y\}$.

Thm: $\tau(\epsilon) \leq T e \ln \epsilon^{-1}$. [Aldous]

Path Coupling

Coupling: Show for all $x, y \in \Omega$, $E[\Delta(\text{dist}(x, y))] \leq 0$.

Path coupling: Show for all u, v s.t. $\text{dist}(u, v) = 1$, that
 $E[\Delta(\text{dist}(u, v))] \leq 0$. [Bubley, Dyer, Greenhill]

Consider a shortest path:

$$x = z_0, z_1, z_2, \dots, z_r = y,$$

$$\begin{aligned} \text{dist}(z_i, z_{i+1}) &= 1, \\ \text{dist}(x, y) &= r. \end{aligned}$$

$$\begin{aligned} \Rightarrow E[\Delta(\text{dist}(x, y))] &\leq \sum_i E[\Delta(\text{dist}(z_i, z_{i+1}))] \\ &\leq 0. \end{aligned}$$

Coupling the Unbiased Chain

Coupling:

Choose same (v, d) in $S \times \{+, -\}$.

The **distance** Ψ_t at time t is the unsigned area between the two configurations.

- $E[\Delta(\Psi_t)] = p(-\#G + \#B) \leq 0$
- $\text{Var} > 0$ if $\Psi_t > 0$;
- $0 \leq \Psi_t \leq n^2$;
- $\Psi_t = 0$ implies $\Psi_{t+1} = 0$.

Then the paths couple quickly, so the MC is rapidly mixing.

Outline

- Sampling paths uniformly: **Multiple paths**

3-colorings

Lattice Paths with **Uniform Bias**

Tile-based self-assembly (a growth model):

A tile can **attach** if 2 neighbors are present and **detach** if 2 neighbors are missing.

Attach rate is higher than the detach rate.

Generating Biased Surfaces

Given $\lambda > 1$:

Repeat:

Choose (v,d) in $S \times \{+,-\}$.

If a square can be added at v ,
and $d=+$, add it;

If a square can be removed at v ,
and $d=-$, remove it w.p. λ^{-1} ;

Otherwise do nothing.

Converges to the distribution:

$$\pi(S) = \lambda^{\text{area}(S)} / Z.$$

Generating Biased Surfaces

z^2

z^d

ASEPs: **Asymmetric** Simple Exclusion Process:

How fast?

Biased Surfaces in Z^d

Q: How long does the biased MC take to converge?

[Benjamini, Berger, Hoffman, Mossel]

$d = 2$; $\lambda > 1$ const, $O(n^2)$ mixing time (optimal).

Biased Surfaces in Z^d

Q: How long does the biased MC take to converge?

[Benjamini, Berger, Hoffman, Mossel]

$d = 2$; $\lambda > 1$ const, $O(n^2)$ mixing time (optimal).

[Majumder, Sahu, Reif]

$d = 2, 3$; $\lambda = \Theta(n)$, poly time.

Biased Surfaces in Z^d

Q: How long does the biased MC take to converge?

[Benjamini, Berger, Hoffman, Mossel]

$d = 2$; $\lambda > 1$ const, $O(n^2)$ mixing time (optimal).

[Majumder, Sahu, Reif]

$d = 2, 3$; $\lambda = \Theta(n)$, poly time.

[Greenberg, Pascoe, R.]

$d = 2, \lambda > 1$ const
 $d \geq 3, \lambda > d^2$ } $O(n^d)$ mixing time.

Biased Surfaces in Z^d

Q: How long does the biased MC take to converge?

[Benjamini, Berger, Hoffman, Mossel]

$d = 2$; $\lambda > 1$ const, $O(n^2)$ mixing time (optimal).

[Majumder, Sahu, Reif]

$d = 2, 3$; $\lambda = \Theta(n)$, poly time.

[Greenberg, Pascoe, R.]

$d = 2, \lambda > 1$ const } $O(n^d)$ mixing time.
 $d \geq 3, \lambda > d^2$

[Caputo, Martinelli, Toninelli]

$d = 3, \lambda > 1$ $O(n^3)$ mixing time.

Coupling the *Biased Chain*

Coupling:

Choose same (v,d) in $S \times \{+,-\}$.

(case 1):

- $$\begin{aligned} E[\Delta(\Psi_+)] &= p (-\text{wt}(\mathbf{G}) + \text{wt}(\mathbf{B})) \\ &= p (-1 - \lambda^{-1} + 1 + \lambda^{-1}) \\ &\leq 0 \end{aligned}$$

Coupling the *Biased Chain*

Coupling:

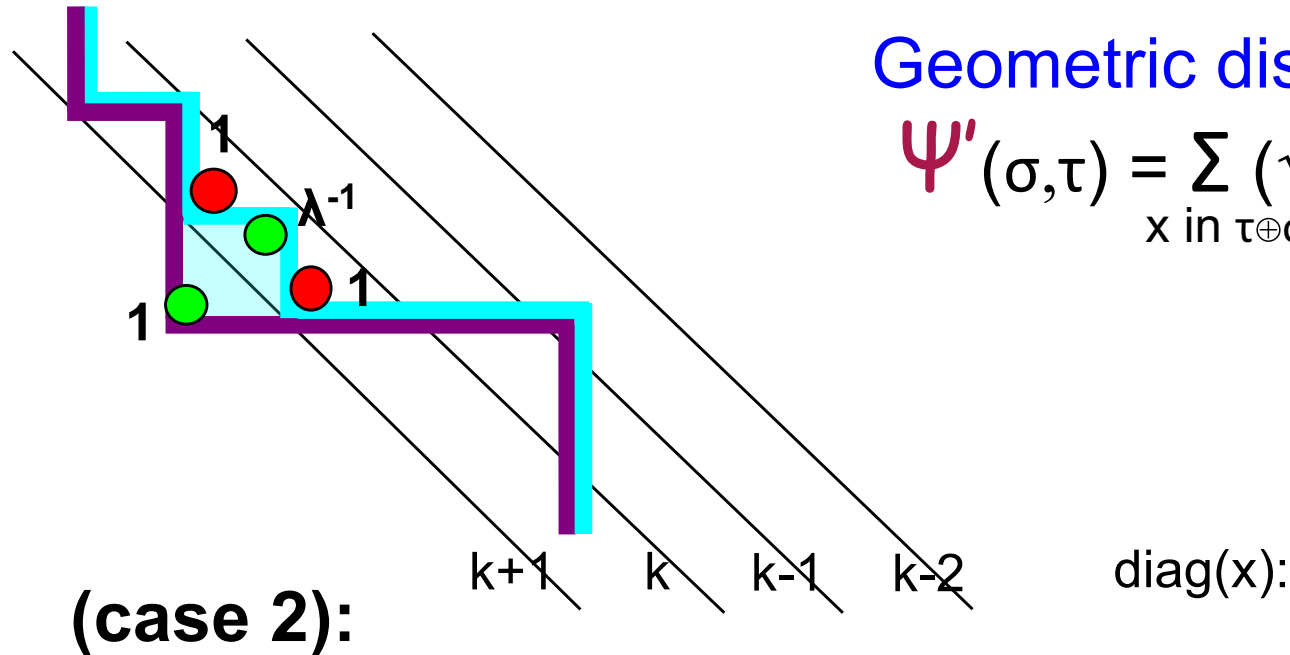

Choose same (v,d) in $S \times \{+,-\}$.

(case 2):

- $$E[\Delta(\Psi_H)] = p (- \text{wt}(\text{G}) + \text{wt}(\text{B}))$$
$$= p (-1 - \lambda^{-1} + 1 + 1)$$
$$> 0$$

Introduce a different metric.

Introduce a New Metric

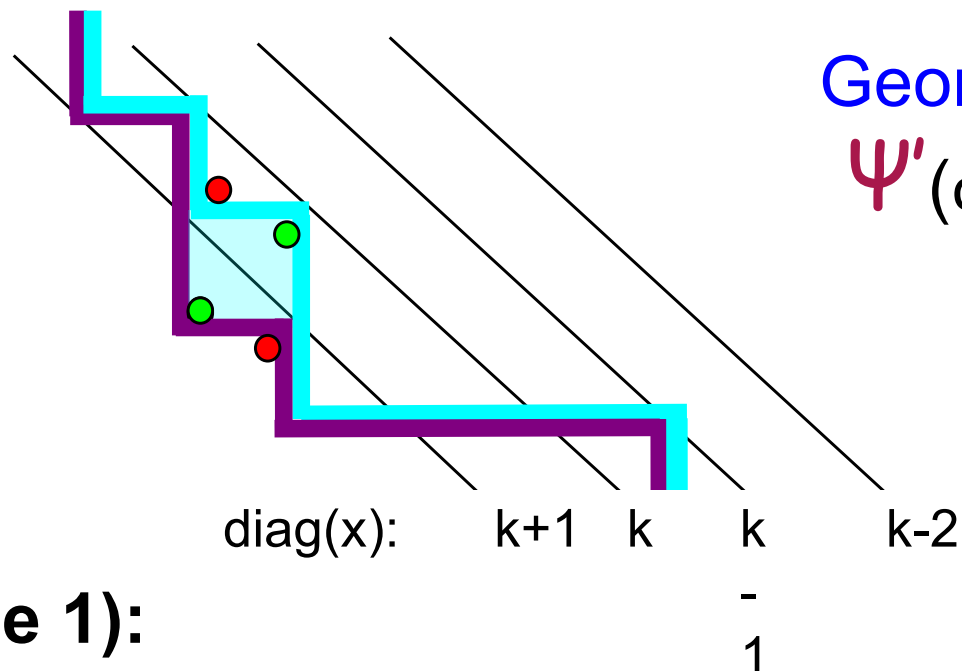

Geometric distance function:

$$\Psi'(\sigma, \tau) = \sum_{x \text{ in } \tau \oplus \sigma} (\sqrt{\lambda})^{\text{diag}(x)}$$

- $E[\Delta(\Psi)] = p (- \text{wt}(\text{G}) + \text{wt}(\text{B}))$
 $= p \lambda^{(k+1)/2} (-1 - \lambda^{-1} + \lambda^{-1/2} + \lambda^{-1/2}) < 0$

Introduce a New Metric

Geometric distance function:

$$\Psi'(\sigma, \tau) = \sum_{x \text{ in } \tau \oplus \sigma} (\sqrt{\lambda})^{\text{diag}(x)}$$

(case 1):

- $E[\Delta(\Psi')] = p (-\text{wt}(\text{G}) + \text{wt}(\text{B}))$
 $= p \lambda^{(k+1)/2} (-1 - \lambda^{-1} + \lambda^{-1/2} + (\lambda^{-1}) \lambda^{1/2}) < 0$

The distance Ψ'_+ is always nonincreasing (in expectation), and by path coupling the chain is rapidly mixing.

Outline

- Sampling paths uniformly
- Paths with uniform bias
- Paths with non-uniform bias

0	1	0	1	0
1	0	1	0	2
0	2	0	2	1

3-colorings

Integer Partitions

Ferrers Diagrams:

Let the **partition number** $p(n)$ be the number of partitions of size n :

$p(i)$: 1, 2, 3, 5, 7, 11, 15, 20, ...

Asymptotic Estimate: $p(n) \sim \frac{1}{4\sqrt{3n}} e^{\pi\sqrt{2n/3}}$

[Hardy, Ramanujan 1918]

Sampling Integer Partitions

Dynamic Programming:

Restricted Partition Number $p(n,k)$:

number of ways to partition n into at most k pieces.

Simple recurrence relation: $p(n,k) = p(n-k, k) + p(n, k-1)$.

Thus we can exactly sample partitions of n using **dynamic programming** and **self-reducibility**.

However, *space* requirements are very large:

partition numbers grow as $\approx e^{O(\sqrt{n})}$

Almost a petabyte for $n \approx 1000000$.

Markov Chains?

Many chains with simple rules converge to the uniform dist'n, but the **mixing time remains open** for all of them.

Ex:

Chain 1: move a square

Chain 2: pick a sub-square and flip

[Aldous 1999], [Berestycki, Pitman 2007]

And many others....

Approaches

Try 1:

$$\Omega_n$$

Try 2:

$$\Omega = \bigcup_{i=1}^n \Omega_i$$

Try 3:

$$\Omega = \bigcup_{i=1}^n \Omega_i, \quad \lambda < 1$$

- Need:
1. The chain is **rapidly mixing**.
 2. **Rejection sampling** is efficient.

Boltzmann Sampling

[Bhakta, Cousins, Fahrbach, R.]

Let Ω be the set of **all** lattice paths in an $n \times n$ region;
and Ω_n the set of lattice paths with **area** n .

Thm: $p_i = |\Omega_i|$ is logconcave
($n > 25$). [DeSalvo, Pak]

- Generate samples σ of Ω with prob. proportional to $\lambda^{\text{area}(\sigma)}$.

So $q_i = p_i \lambda^i$ is also logconcave
(and therefore **unimodal**).

- Setting $\lambda = p_n / p_{n+1}$ gives $q_n = q_{n+1}$.
- So n and $n+1$ must be the modes of the dist'n.

Boltzmann Sampling

[Bhakta, Cousins, Fahrbach, R.]

What about **partition classes** where we do not know if the sequence is logconcave?
(e.g., partitions with at most k pieces,...)

Need: 1. The chain is rapidly mixing.
2. Rejection sampling is efficient.

Thm: If the Markov chain is rapidly mixing **for all λ** ,
then rejection sampling is also efficient for **some λ** !

Boltzmann Sampling

[Bhakta, Cousins, Fahrback, R.]

Define $\lambda_1, \dots, \lambda_m$ and let π_i is the distribution with bias λ_i s.t.:

- $\|\pi_i, \pi_{i+1}\|$ small, for all i ;
- π_1 is concentrated on configurations of size $< n$;
- π_m is concentrated on configurations of size $> n$;
- MC is rapidly mixing, for all λ_i .

Then there exists a λ_i s.t.

$$\Pr(\pi_i \text{ outputs a sample of size } n) > \text{poly}(n).$$

Outline

2	0	2	0	1
0	1	0	1	0
1	0	1	0	2
0	1	0	2	1

3-colorings

Biased Card Shuffling

- Pick a pair of adjacent cards uniformly at random
- Put j ahead of i with probability $p_{j,i} = 1 - p_{i,j}$

Converges to:
$$\pi(\sigma) = \prod_{i < j: \sigma(i) > \sigma(j)} \frac{p_{ij}}{p_{ji}} / Z$$

This is related to “Move-Ahead-One” for self-organizing lists.

[Fill]

Biased Permutations

Question: If the $\{p_{ij}\}$ are **positively biased** ($p_{ij} \geq 1/2 \quad \forall i < j$),
is M always rapidly mixing?

Recall, with **constant bias**:

If $p_{ij} = p \quad \forall i < j$, $p > 1/2$, then M mixes in $\theta(n^2)$ time. [BBHM]

Linear extensions of a partial order: If $p_{i,j} = 1/2$ or $1 \quad \forall i < j$,
then M mixes in $O(n^3 \log n)$ time. [Bubley and Dyer]

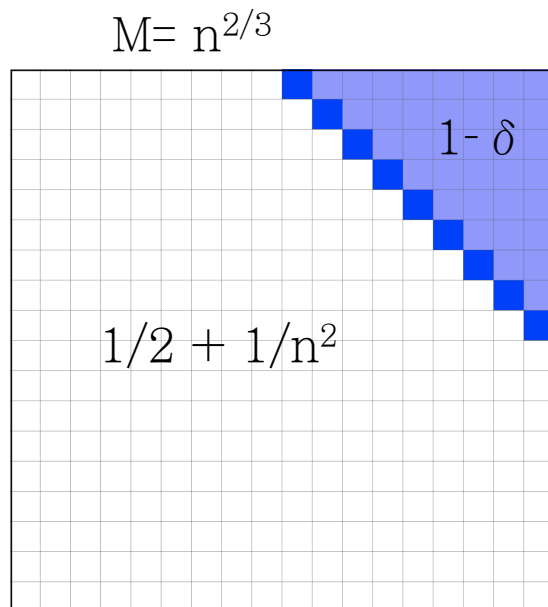

Fast for two classes: **“Choose your weapon”** and **“league hierarchies”** (if *weakly regular*). [Bhakta, Miracle, R., Streib]

Biased Permutations

Question: If the $\{p_{ij}\}$ are **positively biased** ($p_{ij} \geq 1/2 \quad \forall i < j$),
is M always rapidly mixing?

No !!!

[BMRS]

Biased Permutations

Question: If the $\{p_{ij}\}$ are **positively biased** ($p_{ij} \geq 1/2 \quad \forall i < j$),
is M always rapidly mixing?

No !!!

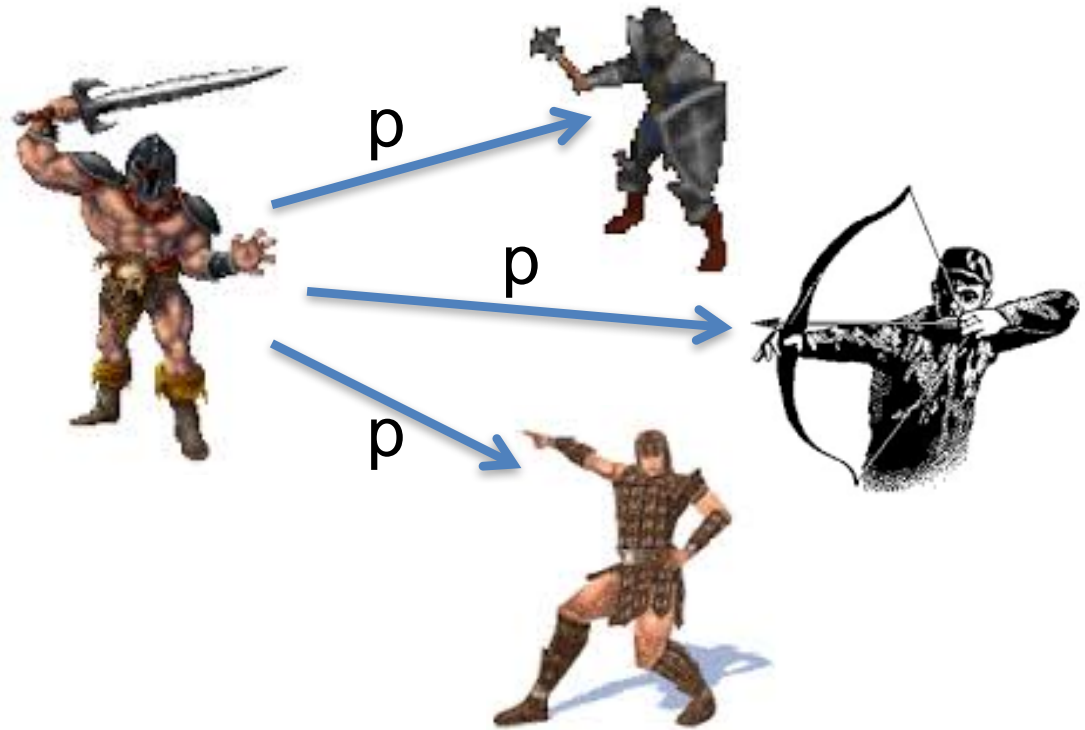

The state space has a "bad cut" so M requires exponential time.
However, most cases do seem fast....

“Choose your weapon”

Given r_1, \dots, r_{n-1} , $r_i \geq 1/2$.

[BMRS]

Thm 1: Let $p_{ij} = r_i \quad \forall i < j$. Then M_{NN} is rapidly mixing.

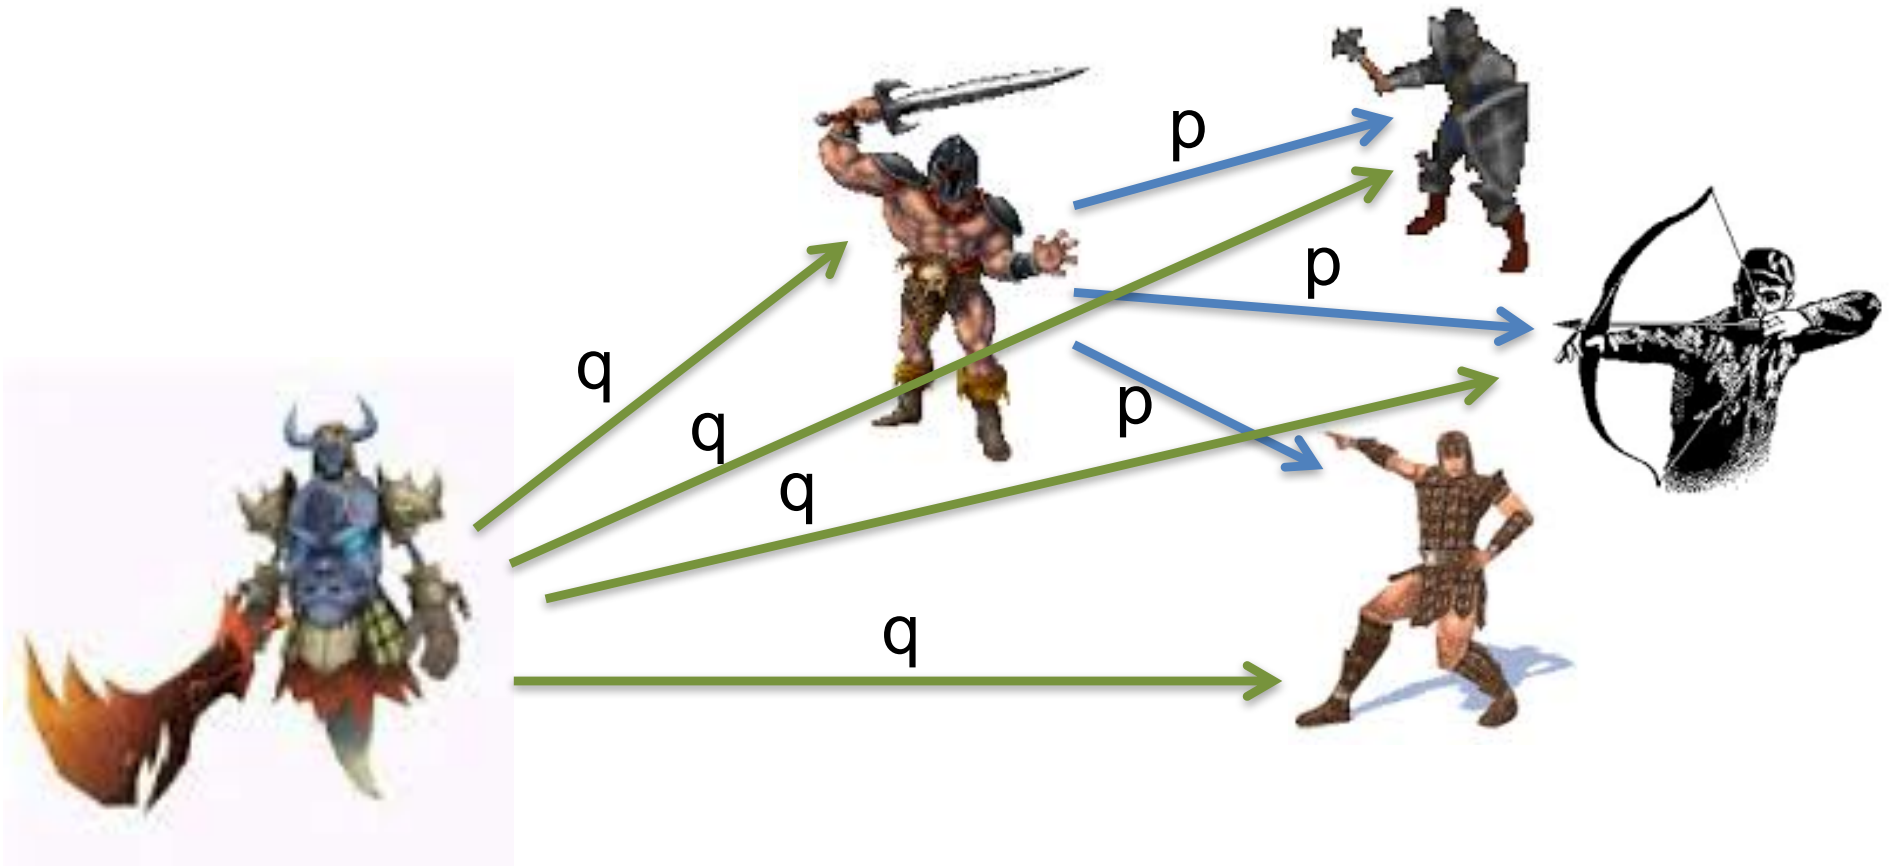

“Choose your weapon”

Given r_1, \dots, r_{n-1} , $r_i \geq 1/2$.

[BMRS]

Thm 1: Let $p_{ij} = r_i \quad \forall i < j$. Then M_{NN} is rapidly mixing.

“League Hierarchies”

Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.

Given $q_v \geq 1/2$ for each *internal* vertex v .

Thm 2: Let $p_{i,j} = q_{i \wedge j}$ for all $i < j$. Then M_{NN} is rapidly mixing.

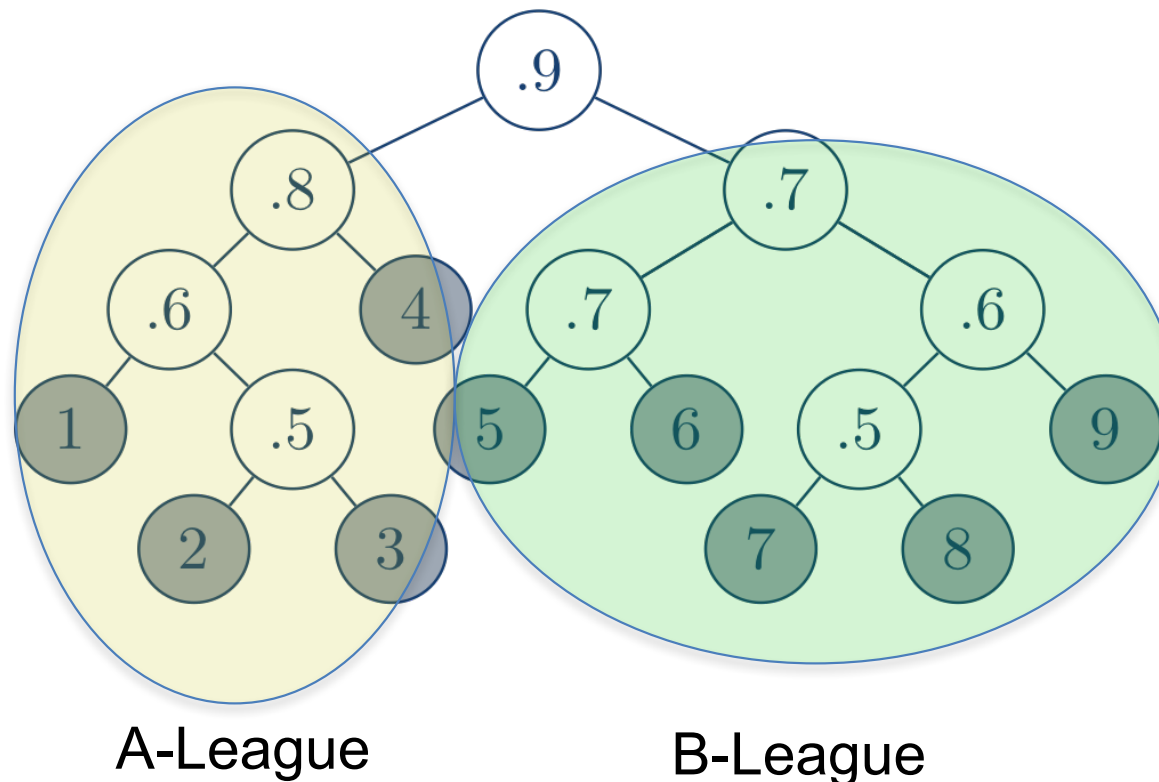

League Hierarchies

Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.

Given $q_v \geq 1/2$ for each *internal* vertex v .

Thm 2: Let $p_{i,j} = q_{i \wedge j}$ for all $i < j$. Then M_{NN} is rapidly mixing.

League Hierarchies

Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.

Let $q_v \geq \frac{1}{2}$ be assigned to each *internal* vertex v .

Thm 2: Suppose $p_{ij} = q_{i \wedge j}$ for all $i < j$ for some labeled binary tree.
Then M_{NN} is rapidly mixing.

Thm 2: Proof sketch

Thm 2: Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.
Let $q_v \geq \frac{1}{2}$ be assigned to each *internal* vertex v .
Let $p_{i,j} = q_{i \wedge j}$ for all $i < j$. Then M_{NN} is rapidly mixing.

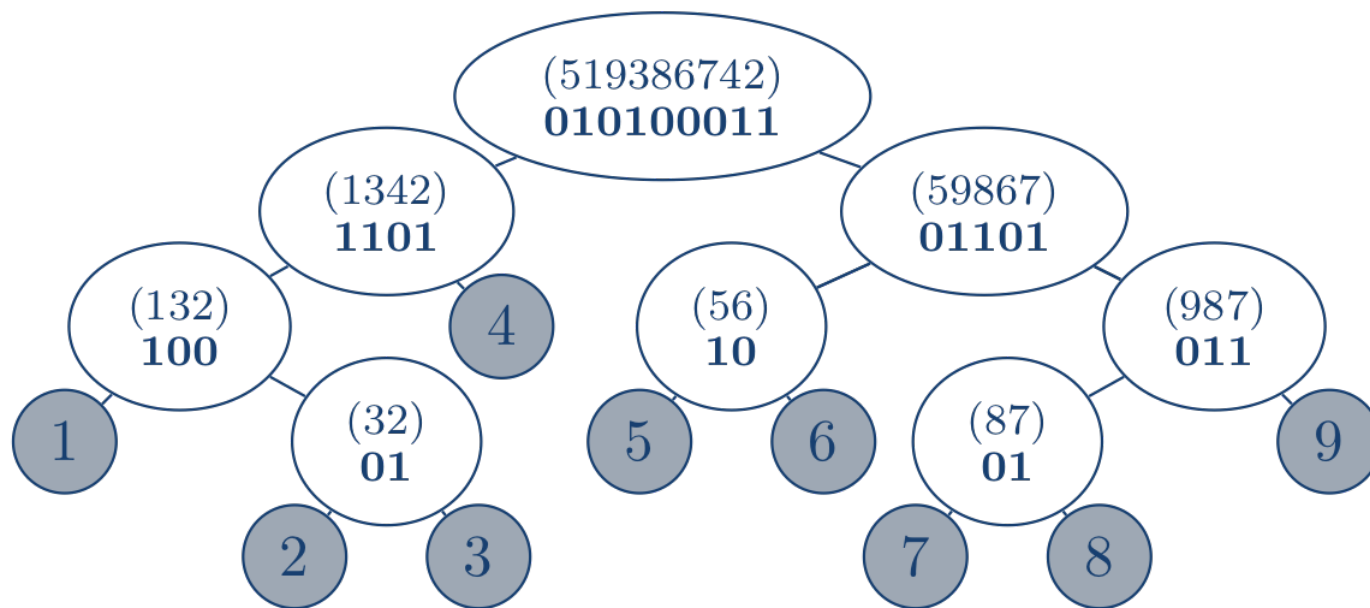

Thm 2: Proof sketch

Thm 2: Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.
Let $q_v \geq \frac{1}{2}$ be assigned to each *internal* vertex v .
Let $p_{i,j} = q_{i \wedge j}$ for all $i < j$. Then M_{NN} is rapidly mixing.

Thm 2: Proof sketch

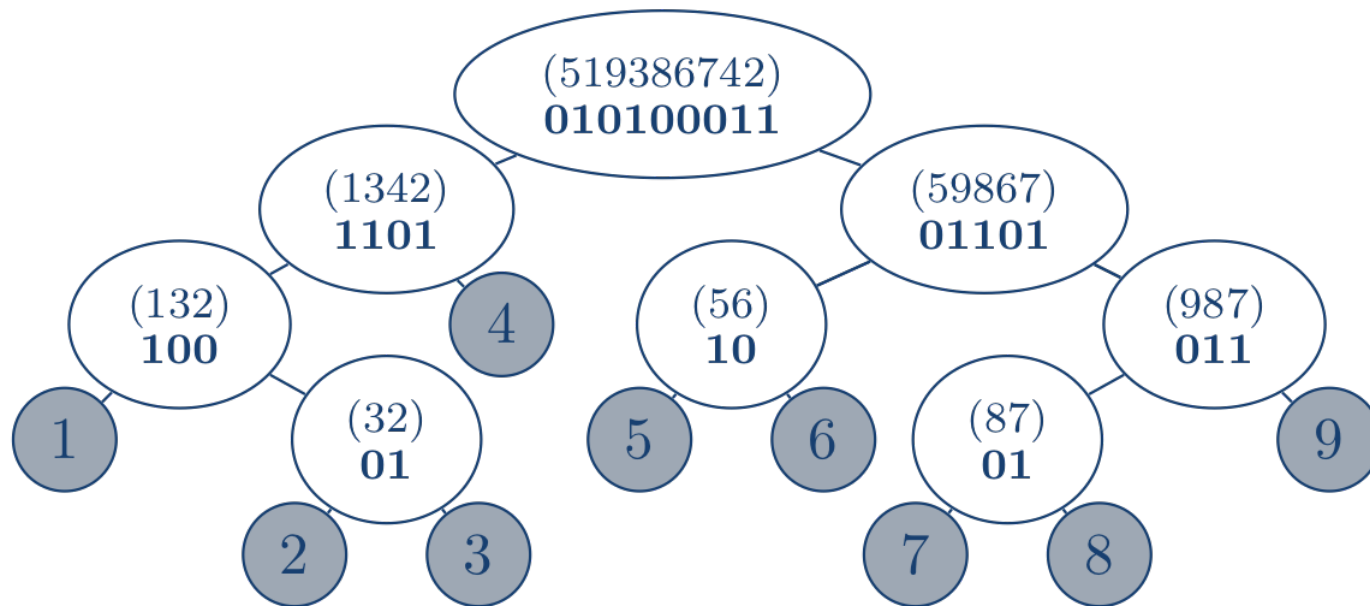

Thm 2: Let T be a binary tree with leaves labeled $\{1, \dots, n\}$.
Let $q_v \geq \frac{1}{2}$ be assigned to each *internal* vertex v .
Let $p_{i,j} = q_{i \wedge j}$ for all $i < j$. Then M_{NN} is rapidly mixing.

Thm 2: Proof sketch

Markov chain M' allows a transposition if it corresponds to an **ASEP** move on one of the internal vertices.

Each **ASEP** is rapidly mixing $\Rightarrow M'$ is rapidly mixing.

M_{NN} is also rapidly mixing if $\{p\}$ is *weakly regular*.

i.e., for all i , $p_{i,j} < p_{i,j+1}$ if $j > i$. (by comparison)

Open Problems

1. **Fill's conjecture**: is M_{NN} always rapidly mixing when $\{p_{ij}\}$ are positively biased and regular?

(i.e., $p_{ij} > \frac{1}{2}$ and p_{ij} is monotonic in i and j)

1'. What about the **special case**:

Given a_1, \dots, a_n "strengths", with $a_i > 0$, let $p_{ij} = a_i / (a_i + a_j)$.

2. When does bias speed up or slow down a chain?

Thank you!
